Introduction - Tensor network

- Partition functions and expectation values of physical quantities can be expressed as a tensor network.

$$Z = \int \mathcal{D}\phi e^{-S[\phi]} = \sum_{\dots, i, j, k, l, m, n, o, \dots} \dots T_{ijkl} T_{mnio} \dots =$$

- Tensors network notation:

$$T_{ijkl} \longrightarrow i \begin{array}{c} k \\ | \\ \bullet \\ | \\ l \\ \end{array} j, F_{abc} \longrightarrow a \begin{array}{c} c \\ | \\ \bullet \\ | \\ b \\ \end{array}$$

$$\sum_l T_{ijkl} F_{jmn} \longrightarrow i \begin{array}{c} k \\ | \\ \bullet \\ | \\ l \\ \end{array} \begin{array}{c} j \\ | \\ \bullet \\ | \\ m \\ \end{array} \begin{array}{c} n \\ | \\ \bullet \\ | \\ \end{array}, \sum_a T_{iaal} \longrightarrow i \begin{array}{c} \bullet \\ | \\ l \\ \end{array} \begin{array}{c} \text{circle} \\ \end{array} \begin{array}{c} a \\ \end{array}$$

Introduction - Tensor renormalization group

- The tensor renormalization group [Levin-Nave, 2007] is a method for the truncation of tensor networks.
- We focus on the higher-order tensor renormalization group (HOTRG) method shown in the figure below,

Introduction Tensor renormalization group

- The isometry matrix can be obtained from the tensor T of the network using the singular value decomposition (SVD).

Entanglement entropy

- Definition of the entanglement entropy of subregion A :

$$S_A = -\text{Tr} \rho_A \log \rho_A, \quad \rho_A = \text{Tr}_B \rho$$

- The reduced density matrix ρ_A of the subregion A can be expressed as a tensor network.

→ We use the HOTRG method for evaluating the reduced density matrix.

Our approach to reduced density matrix [Hayazaki-Kadoh-Takeda-GT, arXiv:2312.xxxxx]

We develop a general method for evaluating the reduced density matrix of the subregion of any spatial size l based on the HOTRG. cf. [Luo-Kuramashi, 2023] for the case of $l = L_x/2$

$$\rho_A(l, L_x)_{ij} \sim$$

For the subregion A
of any size l

Detail of our approach

- The most important point of our method is that we decompose the reduced density matrix ρ_A into a contraction of coarse-grained tensor \tilde{T} and the **boundary factor** B .

- The boundary factor B consists of isometry matrices $U^{(k)}$ and $U^{(k)\dagger}$ which perform the coarse-graining of tensor $T^{(k)}$ in x direction.

Detail of boundary factor B

- For simplicity, we consider the case that $L_x = 2^N$ and $l = 2^0, 2^1, 2^2, \dots, 2^{N-1}$. In this case, the boundary factor $B_{x_1 x'_1 x_2 x'_2 ij}$ for $l = 2^n$ ($0 < n < N$) is given by the product of a contraction of the isometry matrices and a Kronecker delta:

$$\begin{aligned}
 B_{x_1 x'_1 x_2 x'_2 ij} &= \text{Diagram of } B \text{ with inputs } x_1, x'_1, x_2, x'_2 \text{ and outputs } i, j \\
 &= \text{Diagram of } U^{(N-1)}, U^{(N-2)}, \dots, U^{(n+1)} \text{ isometry matrices in a chain, with } U^{(N-1)\dagger}, U^{(N-2)\dagger}, \dots, U^{(n+1)\dagger} \text{ on the left and } U^{(N-1)}, U^{(N-2)}, \dots, U^{(n+1)} \text{ on the right.} \\
 &\quad \text{A red box highlights a Kronecker delta } \delta_{x_2 x'_2} \text{ between } x_2 \text{ and } x'_2. \\
 &= (U^{(N-1)\dagger} U^{(N-2)\dagger} \dots U^{(n+1)\dagger} U^{(n+1)} \dots U^{(N-2)} U^{(N-1)})_{x_1 x'_1 ij} \delta_{x_2 x'_2}
 \end{aligned}$$

$U^{(k)}$: Isometry matrix performing k -th coarse-graining of the tensor network in the x direction

Detail of boundary factor B

- In particular, the boundary factor B becomes trivial when $l = 2^{N-1} = L_x/2$

$$B = \begin{array}{c} x_1 \\ x'_1 \\ x_2 \\ x'_2 \end{array} \begin{array}{c} \diagdown \\ \diagup \\ \diagdown \\ \diagup \end{array} B \begin{array}{c} i \\ j \end{array} = \begin{array}{c} x_1 \\ x'_1 \\ x_2 \\ x'_2 \end{array} \begin{array}{c} i \\ j \\ \text{hook} \end{array} = \delta_{x_1 i} \delta_{x'_1 j} \delta_{x_2 x'_2}$$

$$\rho_A(l, L_x)_{ij} \sim \begin{array}{c} \tilde{T} \\ x_1 \text{---} x'_1 \\ | \quad | \\ x_2 \text{---} x'_2 \end{array} \times \begin{array}{c} x_1 \\ x'_1 \\ x_2 \\ x'_2 \end{array} \begin{array}{c} i \\ j \\ \text{hook} \end{array} = \begin{array}{c} i \text{---} j \\ | \quad | \\ \dots \\ | \quad | \end{array}$$

Numerical results in the two-dimensional Ising model

- We consider the two-dimensional Ising model

$$H = - \sum_{\langle x,y \rangle} s_x s_y, \quad Z = \text{Tr} e^{-\beta H} = \sum_{\dots i,j,k,l,m,n,o,\dots} \dots T_{ijkl} T_{mno} \dots, \quad T_{ijkl} = \begin{array}{c} j \\ | \\ k \text{ --- } \bullet \text{ --- } i \\ | \\ l \end{array}$$

- We set spatial length $L_x = 2^N$, temporal length $L_t = \alpha \cdot 2^N$ and temperature T to the critical temperature T_c .

- We take sufficiently large α and conformally map the plane into a cylinder of spatial length L_x .

- We evaluate the entanglement entropy S_A of subregion A of spatial size $l = 2^n$ in two cases:

- 1 $L_x = 2^{11} = 2048$ and $\alpha = 32$
- 2 fixed $x = 2^n / 2^N$ and $\alpha = 8$

Numerical results in the two-dimensional Ising model

The entanglement entropy S_A of the theory on a cylinder is given by

$$S_A(n, N) = \frac{c}{3} \log \left(\frac{2^N}{\pi \gamma} \sin \left(\frac{2^n}{2^N} \pi \right) \right) + k$$

where γ is a UV regulator, c a central charge, and k a constant.

We extract c from the difference of the entanglement entropy in n using this eq.

1 fixed $L_x = 2048$

$$c = (S(n+1, N) - S(n, N)) \cdot 3 \left(\log \frac{\sin(2^{n+1-N} \pi)}{\sin(2^{n-N} \pi)} \right)^{-1}$$

2 fixed $x = 2^n/2^N$

$$c = (S(n+1, N) - S(n, N)) \cdot \frac{3}{\log 2}$$

Result - Entanglement entropy with fixed $L_x = 2048$ and $\alpha = 32$

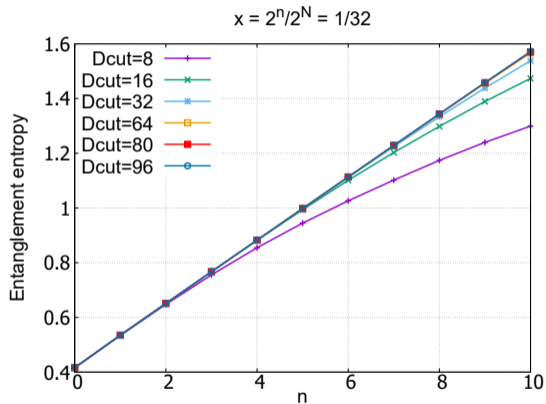

- The entanglement entropy exhibits the behavior consistent with a logarithmic function as expected.

Result - Central charge with fixed $L_x = 2048$ and $\alpha = 32$

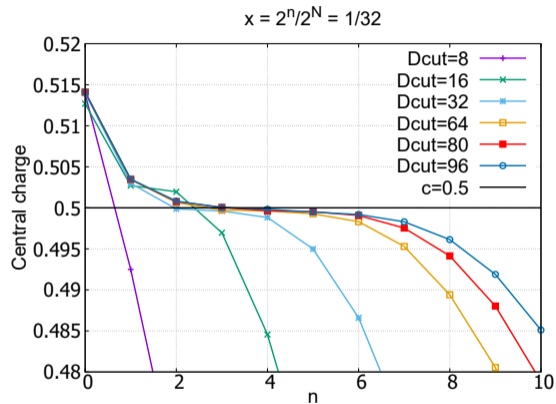

- With sufficiently large D_{cut} , central charge shows the plateau behavior from $n = 3$ to 7.
- Averaging the data of $n = 3, 4, 5, 6,$ and 7 with $D_{\text{cut}} = 96$, we determine the central charge $c = 0.5002(7)$.

Result - Entanglement entropy with fixed $x = 2^n/2^N$ and $\alpha = 8$

- With fixed $x = 2^n/2^N$, the entanglement entropy shows the behavior consistent with a logarithmic function.

Result - Central charge with fixed $x = 2^n/2^N$ and $\alpha = 8$

- In the case of $x = 1/8$, the central charge c exhibits the plateau behavior around $c = 0.5$, while c no longer shows such behavior with $x = 1/32$ due to the extra truncation.
- Averaging the data of $n = 4, 5, 6$, with $D_{\text{cut}} = 96$ and $x = 1/8$, we determine the central charge $c = 0.50013(3)$.

Conclusion and discussion

Conclusion

- We propose a general method based on the HOTRG for evaluating the entanglement entropy.
- Our method makes it possible to examine **the entanglement entropy of a subregion of any spatial size.**
- Applying our method to the two-dimensional Ising model yields results very close to the theoretical value.

Future direction

- Higher-dimensional quantum field theories
- Relation between holography and tensor network
