based on Phys.Rev.D 102 (2020) 1, 011501

Yang-Mills (YM) theories are a cornerstone of current theoretical physics.

A YM theory can be defined for a compact Lie group ${\mathcal G}$

$$\mathcal{G} = SU(N_c), \, Sp(2N_c), \, SO(N_c), \, G_2, \dots \tag{1}$$

where N_c is the number of colors.

At high energy, perturbative theories of gluons.

At low energy, their dynamics is non-perturbative and they are believed to be confining, independently of \mathcal{G} and N_c :

• The Potential between static color sources:

$$V(R) \sim \sigma R, \qquad R \to \infty$$
, (2)

where σ is the string tension.

• Color singlet states called glueballs, labelled by J^{PC} and to relons if the system has finite size.

If confinement is a universal properties of YM theories, Universal properties of the glueball spectrum might help us understand the confining mechanism.

We will argue that the ratio of tensor to scalar glueball masses,

$$R = \frac{m(2^{++})}{m(0^{++})} ,$$

captures some universal property of the spectrum of pure YM theories.

In this contribution we will:

- 1. Enumerate the basic properties of ${\cal R}$
- 2. Discuss the computation of glueball masses in general, report on our estimates for the $Sp(2N_c)$ LGT.
- 2. Summarize (non-exhaustively) the analytical computation of R.
- 3. Discuss some ideas related to the universality of R.

An energy momentum tensor (EMT) $T_{\mu\nu}$ can be defined in any Lorentz-invariant theory.

The EMT can be decomposed in its trace and tensor parts, of masses m_0 and m_T , and the ratio m_T

$$R = \frac{m_T}{m_0}$$

is thus:

- well defined and scheme independent.
- computable.
- not explicitly dependent on internal symmetries.

It makes sense to compare R for different theories. In particular, for glueball states of YM theories

$$R = \frac{m(2^{++})}{m(0^{++})} ,$$

with different gauge groups and different N_c .

・ロト ・日ト ・ヨト ・ヨト

The spectrum from the lattice $_{\rm Definition \ of \ LGT}$

On hypercubic lattice of spacing a we define the *link variable*.

$$U_{\mu}(x) = \exp\left(\imath \int_{x}^{x+\hat{\mu}} \mathrm{d}\lambda^{\mu} \ \tau^{A} A^{A}_{\mu}(\lambda)
ight) \,.$$

We adopt the Wilson action defined as

$$S_{\rm W} \equiv \beta \sum_x \sum_{\mu < \nu} \left(1 - \frac{1}{2N} \, \Re \, \mathrm{Tr} \, \mathcal{P}_{\mu\nu}(x) \right) \; ,$$

where $\mathcal{P}_{\mu\nu}(x) \equiv U_{\mu}(x)U_{\nu}(x+\hat{\mu})U_{\mu}^{\dagger}(x+\hat{\nu})U_{\nu}^{\dagger}(x)$ is the plaquette variable and $\beta = 2N/g_0^2$, g_0 coupling of the YM theory at scale a.

Ensembles of configurations at (β, L) can be obtained by sampling

$$Z(\beta) = \int \left[\mathcal{D}U \right] \exp\left(-S_W\left[U\right]\right) \;,$$

with a combination of HeatBath (HB) and OverRelaxation (OR) algorithms.

Implementations of the HB and OR algorithms for $Sp(2N_c)$ can be easily obtained from that of $SU(2N_c)$.

イロト イヨト イヨト イヨト

The symplectic group $Sp(2N_c)$ can be defined as a subgroup of $SU(2N_c)$,

$$U \in Sp(2N_c) \iff \left\{ U \in SU(2N_c) / \Omega^{\dagger} U \Omega = U^* \right\}$$
(3)

where Ω is the symplectic matrix.

As direct consequences of the definition:

- $Sp(2) \simeq SU(2)$.
- $\bullet\,$ The group is pseudo-real, every IRREP is unitarily equivalent to its complex conjugate. As a consequence, C=1
- The block structure of Ω is inherited by $Sp(22N_c)$ matrices,

$$U = \begin{bmatrix} A & B \\ -B^* & A^* \end{bmatrix}$$
(4)

イロト イヨト イヨト イヨト

with

$$\begin{cases} A^{\dagger}A + B^{\dagger}B = \mathbb{I}, \\ A^{T}B = B^{T}A, \end{cases} A, B \in \mathbb{C}^{N \times N}$$
(5)

• The Cabibbo-Marinari update algorithm can be adjusted from the case of $SU(2N_c)$.

In the continuum, the confined spectrum is composed of

- Glueballs, labelled by J^P .
- To relons of mass $m(L) \sim \sigma L$ for a wrapping direction of size L

On the lattice, glueball states are labelled by IRREPs of the octahedral group, also called *channels*[8]:

$$R^P = A_1^{\pm}, A_2^{\pm}, E^{\pm}, T_1^{\pm}, T_2^{\pm}$$

In the continuum limit

$$m(A_1^+)a \to m(0^+), \quad m(E^+)a, m(T_2^+)a \to m(2^+)$$
.

and, if rotational invariance is to be reestablished, as $a \to 0$ we must have

$$m(E^{\pm})a \to m(T_2^{\pm})a$$

States $|\Psi\rangle$ are obtained as $|\Psi\rangle = O(t)|\Omega\rangle$ with,

$$O(t) = \sum_{\vec{x}} O(\vec{x}, t), \quad O(\vec{x}, t) = \operatorname{Tr} U_{\mathcal{C}}(\vec{x}, t) , \qquad (6)$$

where:

- O is a single trace operator: it creates a single glueball state,
- \mathcal{C} is a closed spacelike lattice path transforming in \mathbb{R}^P ,
- Glueballs for contractible paths, Torelons for non-contractible paths,
- The sum over space projects on the zero momentum subspace,

The mass $m(\mathbb{R}^P)$ is obtained from the large t behaviour of euclidean correlators, where the smallest energy dominates

$$C(t) = \frac{\langle R^P | e^{-\mathcal{H}t} | R^P \rangle}{\langle R^P | R^P \rangle} \sim |c_0|^2 e^{-m(R^P)t} , \quad t \gg 1/m(R^P) , \tag{7}$$

where \mathcal{H} is the Hamiltonian of the system.

イロト イヨト イヨト イヨ

We have the problem an exponentially decaying signal-to-noise ratio at large t. Our only hope is to maximize $|c_0|^2$ with a clever choice of operators.

We perform a variational computation, looking for the $v_i \in \mathbb{C}$ in

$$\Phi(t) = \sum_{i} v_i O_i^{R^P}(t) .$$
(8)

for which

$$am_{\rm var}(\tau) = -\frac{1}{\tau} \log \left\{ \min_{v_i \in \mathbb{C}} \frac{\langle \Omega | \Phi(0)^{\dagger} e^{\mathcal{H}\tau} \Phi(0) | \Omega \rangle}{\langle \Omega | \Phi(0)^{\dagger} \Phi(0) | \Omega \rangle} \right\},\tag{9}$$

where τ is a time chosen for minimization.

The creation of the variational basis $\left\{O_i^{R^P}\right\}$ of operators can be automatized and can also include smeared-blocked operators.

The mass $m(\mathbb{R}^P)$ can be obtained from the correlator of the optimal operators at large t,

$$\tilde{C}(t) \sim |\tilde{c}|^2 e^{-m(R^P)t}$$
 (10)

・ロト ・日ト ・ヨト ・ヨト

Ensembles of configurations were obtained for each $Sp(2N_c)$ with $N_c = 1, 2, 3, 4$:

- At a coupling β and on a lattice of dimensions $L \times L^3$ with p.b.c in every direction, for various values of (β, L) .
- 10000 thermalized configurations were stored for later analysis

For each ensemble, the masses $m_{\ell}R^P$ and σ are determined variationally from a basis of ~ 200 smeared-blocked operators.

The finite volume effects are put under control and the continuum limit is obtained from

$$\frac{m(R^P)}{\sqrt{\sigma}}(a) = \frac{m(R^P)}{\sqrt{\sigma}}(0) + c_0(R^P)\sigma a^2 .$$
 (11)

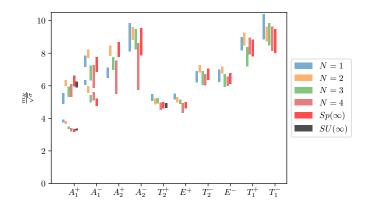

The large-N limit can be obtained from¹

$$\frac{m(R^P)}{\sqrt{\sigma}}(N) = \frac{m(R^P)}{\sqrt{\sigma}}(\infty) + \frac{c_1(R^P)}{N} .$$
(12)

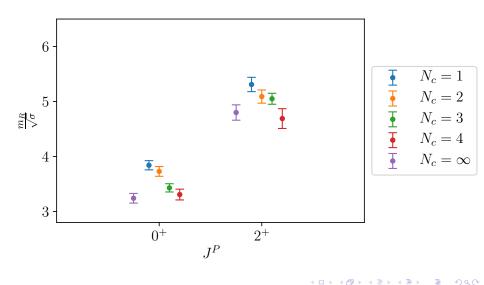

The results can be compared with $SU(N_c)$, $SO(N_c)$ at D = 3 + 1 and D = 2 + 1 already present in the litterature.

・ロト ・日ト ・ヨト ・ヨト

¹Note that this is different from $SU(N_c)$!

- $SU(\infty)$ and $Sp(\infty)$ yield compatible masses in the lightest channels.
- $m(0^+)$ is obtained from the A_1^+ channel.
- $m(E^{\pm})$ and $m(T_2^{\pm})$ are compatible.
- $m(2^+)$ is obtained as the weighted average of $m(E^+)$ and $m(T_2^+)$.

Analytical results can be obtained in the strict $N_c = \infty$ limit.

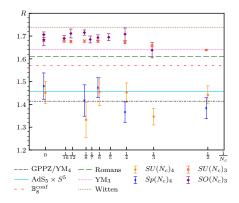

In D = 3 + 1[4, 2, 3, 11, 10],

Model	R
$GPPZ/YM_4$	$\sqrt{2}$
$AdS_5 \times S^5$	1.46
Witten	1.74
Romans	1.61

While in D = 2 + 1[5, 7],

Model	R
\mathbb{B}_8^{conf}	1.57
\tilde{YM}_3	1.64

イロト イヨト イヨト イヨト

- A remarkable agreement between $GPPZ/YM_4$, $AdS_5 \times S^5$ and the $SU(N_c)$, $Sp(2N_c)$ lattice data[9, 6, 1].
- Circle reductions of Romans supergravity and the Witten model predict a value of R which is not compatible with lattice data.
- At D = 2 + 1 R is slightly underestimated with respect to lattice data.

・ロト ・日ト ・ヨト

It is natural to start from universal principles:

1. Scale invariance: If the scalar glueball and dilaton are identified,

$$m_D^2 = \beta f_D^2 \tag{13}$$

where m_D is the dilaton mass, f_D its decay constant, and β a non-universal constant. 2. Perturbative Unitarity: The dilaton scattering amplitude is

$$\mathcal{M}(2\sigma \to 2\sigma) \sim \frac{-1}{(\alpha f_D)^4} (s^2 + t^2 + u^2)$$
, for $E_{\rm CM} \gg m_D$ (14)

where α is a non-universal dimensionless constant. At high energy, unitarity is lost. It can be recovered with the exchange of a spin-2 massive field of mass m_T ,

$$m_T^2 = \alpha \kappa^2 f_D^4 \ . \tag{15}$$

where κ is the universal coupling of the spin-2 field to the dilaton EMT.

If the spin-2 massive field is identified with the tensor glueball,

$$R^2 = \frac{m_T^2}{m_0^2} = \kappa f_D^2 \frac{\alpha}{\beta} \tag{16}$$

APLAT 2020

15 / 16

where α and β are non-universal, in principle computable in the EFT. Lattice data shows the non-universalities cancel.

- $\bullet~R$ is well defined and computable for a large set of theories both on the lattice and analytically.
- In Lattice data obtained at D = 3 + 1 and D = 2 + 1 for the $Sp(2N_c)$ LGT shows no dependence of R on N_c .
- Lattice measurements taken from the litterature are supportive of the idea that R only depends on the dimensionanility of space-time.
- Comparison with analytical calculations performed at $N_c = \infty$ gives mixed results: remarkable agreement in many cases but incompatibilities in two cases. This non exhaustive list of results must be enlarged.

Thank you for your attention!
